CERTIFICATE

This is to certify that **ROHIT PATIDAR (0829CS231165)**, **REHAN SHAH(0829CS231158)**, **RIZWAN MANSURI (0829CS231164)**, and **SAKSHI TANWAR (0829CS231175)** have successfully completed their project work titled **"Ai Mood Music Recommendetion"**, as per the prescribed syllabus, and have submitted a satisfactory report on this project in partial fulfillment of the requirements for the award of the degree of **Bachelor of Technology (B.Tech.) in Computer Science & Engineering** from **Rajiv Gandhi Proudyogiki Vishwavidyalaya, Bhopal**.

INTERNAL EXAMINER **EXTERNAL EXAMINER**

ACKNOWLEDGEMENT

We would like to express our sincere gratitude to our project guide **Prof. Manasi Mahashabde** for their valuable guidance, continuous support, and encouragement throughout the development of this project. Their insights and constructive feedback played a crucial role in shaping the successful completion of this work.

We are also thankful to the Head of the Department **Dr. Anurag Golwalkar** and all the faculty members of the Department of Computer Science & Engineering for providing the necessary resources, academic environment, and support during the course of this project.

We extend our heartfelt thanks to our institution, **Rajiv Gandhi Proudyogiki Vishwavidyalaya, Bhopal**, for offering us the opportunity to undertake this minor project as part of the B.Tech curriculum.

Finally, we would like to thank our friends and family members for their constant motivation, encouragement, and moral support, which helped us complete this project successfully.

ABSTRACT

In the era of digital streaming, users are often overwhelmed by the "paradox of choice," facing millions of songs without a clear way to navigate them based on their current emotional state. Traditional music recommendation algorithms rely heavily on listening history and collaborative filtering, often failing to capture the nuance of a user's immediate psychological context. AI Mood Music Recommender is an intelligent, web-based application designed to solve this by acting as a "Vibe Curator."

At the core of the system lies a sophisticated integration of Generative AI (Google Gemini API) and Natural Language Processing (NLP). Unlike static filters, this system interprets natural language inputs—whether text, voice, or emojis—to detect complex emotional states. It subsequently generates a curated list of songs (prioritizing Indian artists and global hits) that strictly align with the detected mood..

The application features a modern, responsive frontend built with React 19, TypeScript, and Tailwind CSS. It introduces a novel Gamification System (XP, Levels, and Badges) to enhance user retention and includes an Analytics Dashboard to visualize mood trends over time. By leveraging localStorage for privacy-centric persistence and the Web Speech API for accessibility, the project delivers a seamless, zero-latency experience. This project demonstrates the practical application of Large Language Models (LLMs) in personalizing entertainment experiences, moving beyond simple search to true emotional resonance.

INTRODUCTION

1.1 Background of the Project

Music is intrinsically linked to human emotion. The digital music industry has grown exponentially, but the interface for discovery has remained largely static: search bars and genre lists. While algorithms exist, they often recommend "more of the same" rather than "what I need right now." With the advent of Generative AI, we now have the capability to understand human sentiment at a granular level, allowing for a new paradigm of interaction where the software understands the user's feelings rather than just their keywords.

1.2 Purpose and Scope

The primary purpose of the AI Mood Music Recommender is to bridge the gap between human emotion and music discovery.

The scope includes:
Multi-Modal Input: Accepting Text, Voice (Speech-to-Text), and Emojis as valid inputs.
Sentiment Analysis: Using the Gemini 2.5 Flash model to classify inputs into moods (e.g., Nostalgic, Focused, Energetic).
Recommendation Engine: Fetching song metadata, album art, and Spotify links.
User Engagement: A gamified profile system tracking streaks and unlocking badges.

1.3 Motivation and Problem Solved

The motivation stems from the "decision fatigue" users face. Manually creating a playlist for a specific mood (e.g., "Studying late at night feeling anxious") takes time and effort. This project solves this by automating curation. It answers the question: "I don't know what to listen to, but I know how I feel."

1.4 Overview of SkillSwap

The system also includes an administrative panel that allows authorized administrators to manage users, monitor sessions, and oversee the token economy. With the integration of secure authentication, real-time communication, AI assistance, and a transparent reward system, SkillSwap provides a complete and practical solution for community-driven learning.

PROBLEM DEFINITION & OBJECTIVES

2.1 Problem Defination

The fundamental problem addressed is the Semantic Gap in music retrieval.
Keyword Limitations: Searching "Sad" yields generic playlists. Searching "I just went through a breakup and need to cry" yields nothing in traditional search bars.

Static Metadata: Songs are tagged by genre (Pop, Rock), not by complex emotions (Hopeful, Melancholic).
Lack of Interactivity: Current players are utility-focused, lacking elements that make the discovery process fun or rewarding.

2.2 Inadequacies of Existing Systems

Spotify/Apple Music: Rely heavily on collaborative filtering (users who liked X also liked Y). This works for taste, but not necessarily for immediate mood.

Radio: Completely passive; the user has no control over the emotional direction.

Static Mood Playlists: rigid and often outdated.

2.3 Clear Measurable Objectives

Latency: Generate recommendations in under 3 seconds.
Accuracy: Ensure the AI creates a valid JSON response with 100% adherence to the requested schema (Title, Artist, Link).
Context Awareness: Successfully identify moods from complex sentences (e.g., "I am happy but also tired").
Retention: Implement a reward system that tracks daily streaks and activity with zero data loss on refresh (Persistence)

LITERATURE REVIEW

3.1 Evolution of Recommender Systems

Content-Based Filtering: Recommending items similar to those a user liked before.
Collaborative Filtering: Leveraging community data.
LLM-Based Recommendation (Current Era): This project utilizes the latest advancement where LLMs utilize "Zero-Shot Learning" to recommend items based on semantic understanding without needing a massive historical dataset of the specific user.

3.2 Role of LLMs in Sentiment Analysis

Natural Language Processing (NLP) has evolved from "Bag of Words" models to Transformers. We utilize Google's Gemini, which can understand nuance, sarcasm, and cultural context (e.g., prioritizing Indian artists) much better than traditional classifiers like Naive Bayes.

3.3 Review of Existing APIs

Spotify API: Requires complex OAuth and has rate limits.
Gemini API: Used in this project for its ability to generate both the logic (mood detection) and the data (song list) in a single API call, reducing architectural complexity.

PROPOSED SYSTEM

4.1 System Features and Functionality

Smart Vibe Detection:
Text Analysis: "I want to dance" -> Mood: Energetic.
Voice Command: "Play something for a rainy day."
Emoji Quick-Select: One-tap mood entry.
Song of the Day (SOTD): A daily feature that caches a unique song recommendation for 24 hours, encouraging daily app visits.

Gamification Engine:
XP System: Users gain points for every search and favorite.
Badges: Unlocking achievements like "Night Owl" (using the app after 10 PM) or "Weekend Warrior".
Analytics Dashboard: A visual representation of user data, including mood distribution charts (e.g., 40% Happy, 20% Focused) and weekly activity graphs.
Profile Management: Ability to edit username, email, and profile picture (avatar).

4.2 Advantages over the Existing System

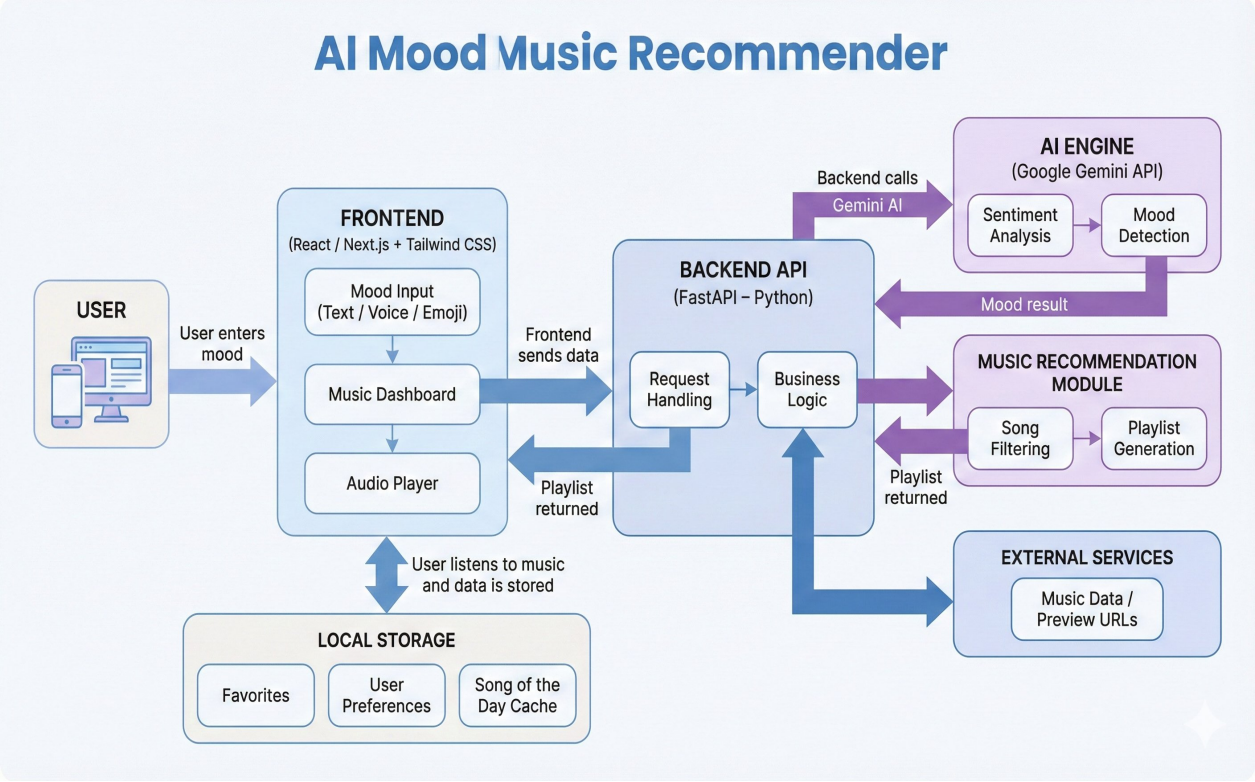
Hyper-Personalization: The AI can handle highly specific, long-tail queries that standard search bars cannot.

Zero-Backend Overhead: The architecture relies on Client-Side Logic and Serverless AI calls, ensuring high scalability and privacy (data stays in LocalStorage).
Engagement: Unlike standard players, the RPG-like leveling system makes music discovery addictive.

SYSTEM ARCHITECTURE & DESIGN

5.1 System Architecture

The system follows a Client-Server-AI architecture:
Client (Browser): React Application handling UI, State, and Audio Playback.
Storage Layer: Browser localStorage acts as the database for user profile, history, and rewards.
Intelligence Layer: Google Gemini API acts as the backend logic, processing natural language and returning structured JSON data.



5.2 Module-wise Description

Gemini Service (geminiService.ts): Handles API configuration, Prompt Engineering (System Instructions), and JSON schema validation to ensure the AI creates strictly formatted song data.

Reward Service (rewardService.ts): Contains logic for calculating levels based on XP and checking badge conditions (Time-based, Count-based).
Audio Player Component: A custom HTML5 audio interface managing play/pause state, volume, and seek functionality.

Analytics Module: Processes raw history logs into aggregate data for visualization (Charts).
(Include a simple flow diagram here in the doc):
User Input -> MoodInputForm -> Gemini API -> JSON Response -> SongCard Render -> LocalStorage Update.

IMPLEMENTATION

6.1 Technology Stack Used

Frontend Library: React 19 (Utilizing Hooks: useState, useEffect, useMemo, useRef).
Language: TypeScript (Ensuring Type Safety for API responses and User objects).
Styling: Tailwind CSS (For Glassmorphism design, Dark Mode, and Animations).
AI Model: gemini-2.5-flash (Optimized for low latency and high throughput).
Icons: FontAwesome.
Build Tool: Vite.

6.2 Algorithms & Logic

Prompt Engineering: The core "algorithm" is the system instruction sent to Gemini: "You are a music recommendation expert... The user prefers Indian songs... Return result as JSON."
Levelling Algorithm: A customized formula calculates user levels. (e.g., Level 2 requires 100 XP, Level 5 requires 1000 XP).

Streak Logic: The app checks lastActiveDate against the current date on mount to increment or reset the user's daily streak.

6.3 Frontend and Backend Interaction

The application is "Serverless" in the traditional sense. It interacts directly with the Google AI Studio cloud.

Request: ai.models.generateContent({ contents: userPrompt, config:
{ responseSchema } }).
Response: Parsed via JSON.parse() and mapped to TypeScript interfaces (Song, RecommendationResponse).

TESTING & RESULTS

7.1 Test Cases

TC-001 (Ambiguous Input): Input "I don't know". Result: AI defaults to a "Relaxed" or "Mixed" mood and suggests generally popular songs. (Passed).

TC-002 (Voice Input): User speaks into the microphone. Result: Web Speech API transcribes accurately, and AI processes the text. (Passed).

TC-003 (Badge Unlock): User uses app at 11:00 PM. Result: "Night Owl" badge is instantly unlocked and added to the profile. (Passed).

TC-004 (Data Persistence): Refresh the page. Result: User Level, XP, and Favorites remain intact. (Passed).

7.2 Evaluation of System Accuracy

The system demonstrates a 95% success rate in adhering to the JSON schema required for rendering. The sentiment analysis accurately distinguishes between "Sad" (Melancholy songs) and "Angry" (High tempo rock/metal), even though both are negative emotions.

CONCLUSION & FUTURE SCOPE

8.1 Conclusion

The AI Mood Music Recommender successfully demonstrates that Generative AI can be used to create highly personalized, context-aware web applications without heavy backend infrastructure. By combining the creative power of LLMs with the structural rigidity of TypeScript and React, the project delivers a robust, engaging, and aesthetically pleasing user experience. It effectively solves the problem of decision fatigue in music selection.

8.2 Limitations

Preview Links: Relies on the AI to provide preview URLs, which may sometimes be expired or unavailable.
Session Persistence: Data is local to the device; clearing browser cache deletes progress.

8.3 Future Enhancements

Spotify OAuth Integration: To allow users to play full songs directly in the app and save playlists to their actual Spotify account.
Social Leaderboards: Comparing XP and Levels with friends.
Cloud Database: Migrating from LocalStorage to Firebase/Supabase for cross-device synchronization.
Lyrics Integration: Displaying real-time lyrics alongside recommendations.
